Backport to 3.9: cherry-picking failed — conflicts found

✖ Failed to cleanly apply [33ccdfb](#) on top of patchback/backports/3.9/33ccdfb0a12690af5bb49bda2319ec0907fa7827/pr-8074

Backporting merged PR [#8074](#) into master

1. Ensure you have a local repo clone of your fork. Unless you cloned it from the upstream, this would be your **origin** remote.
2. Make sure you have an upstream repo added as a remote too. In these instructions you'll refer to it by the name **upstream**. If you don't have it, here's how you can add it:

```
$ git remote add upstream https://github.com/patchback/backports/3.9/33ccdfb0a12690af5bb49bda2319ec0907fa7827/pr-8074
```

3. Ensure you have the latest copy of upstream and prepare a branch that will hold the backported code:

```
$ git fetch upstream
$ git checkout -b patchback/backports/3.9/33ccdfb0a12690af5bb49bda2319ec0907fa7827/pr-8074
```

4. Now, cherry-pick PR [🔗 Improve validation in HTTP parser #8074](#) contents into that branch:

```
$ git cherry-pick -x 33ccdfb0a12690af5bb49  31
```

If it'll yell at you with something like `fatal: Commit 33ccdfb0a12690af5bb49bda2319ec0907fa7827 is a merge but no -m option was given.`, add `-m 1` as follows instead:

```
$ git cherry-pick -m1 -x 33ccdfb0a12690af5  od
```

5. At this point, you'll probably encounter some merge conflicts. You must resolve them in to preserve the patch from PR [🔗 Improve validation in HTTP parser #8074](#) as close to the original as possible.
6. Push this branch to your fork on GitHub:

```
$ git push origin patchback/backports/3.9/  If
```

7. Create a PR, ensure that the CI is green. If it's not — update it so that the tests and any other checks pass. This is it! Now relax and wait for the maintainers to process your pull request when they have some cycles to do reviews. Don't worry — they'll tell you if any improvements are necessary when the time comes!

Hey @pajod, could you expand what this comment refers to? Does the `utf8sep` variable contain a value that matches all the listed cases? I'm rather confused. Or did you mean to test different cases but added just one?

pajod on Jan 29, 2024 • edited

Contributor

That utf8sep has those properties (and LTR), a popular choice for being multiple edge cases in one. None of which are strictly needed for.. *comparing to the literal ASCII dot* as we do here, but some of which I expect to regain relevance on future refactoring.

@pajod FYI it's much cleaner to use the `@pytest.mark.xfail` decorator since it allows pytest to make the decisions earlier in the process.

pajod on Jan 29, 2024 • edited

Contributor

But that *only* explains why a llhttp-only code coverage report complains!? There is something much more wrong here. Like, *I completely broke that test* levels of wrong.

Edit: Sorry, I did. Four times. I meant to acknowledge (in [two cases, expected to be changed](#)) behaviour differences of the C parser, while keeping my tests parametrized to keep running both parsers anyway. But each time I copied the `not isinstance(response, HttpResponseParserPy)` line where it should say `not isinstance(parser, HttpRequestParserPy)`. And mypy would have told me, if not for that `Any` and the duplicate use of the `response` identifier (global scope function but also function scope variable)

Yeah, I noticed there was no coverage on these tests for some reason. Something to look at later.

webknjaz on Jan 29, 2024

Yep. I started looking into the coverage drop and that's how I noticed this thing.

FWIW we *really* should refactor how the tests with and without extensions are parametrized/generated, like I did in multidict recently. Essentially, there was an import loop in some places in tests that prevented C-extension tests from being executed ([aio-lib/multidict#837](#) / [aio-lib/multidict#915](#) / <https://multidict.aio-lib.org/en/latest/changes/#contributor-facing-changes>). So I fixed that by having an explicit global option for requiring one mode or the other, with a collection of fixtures reused everywhere and zero magic around import attempts and handling failures in weird ways.

Another thing I configured is the module classification in Codecov with different expected coverage thresholds — the goal should be that tests get 100% coverage in every CI run (from all jobs combined, of course). And the actual project code coverage should be measured as a separate metric. Currently, a global threshold value allows coverage to drop in tests if it's compensated by coverage in the project, meaning that we may be gaining more dead code (read: tests that are never executed), which results in a false sense of things being tested, when they aren't.
